

Trilobites are extinct, hard-shelled marine animals that lived in the seas millions of years ago. They evolved at the beginning of the Palaeozoic Era (over 500 million years ago) and went extinct during the late Permian period (248 million years ago). The trilobite gets its name because its body is divided into three main segments. Trilobites are arthropods which means 'joint footed'.

1. Cut out the body, gills and legs.
2. Fold along the dotted lines.
3. Glue gills to underside of body.
4. Glue legs to underside of gills.
5. Glue antennae to underside of head.
